**Abstract**
Creativity is recognized as a fundamental skill in the information society but many countries lack a school model that is able to promote the creative potential of their students. In mathematics, the development of higher-level skills, such as creativity, is not possible through direct teaching practices. The digital revolution brought a set of different technological tools with great potential to engineer collaborative work environments and to mediate communication in the classroom. The main objective of this qualitative is to evaluate the potential of digital technologies to construct collaborative environments and as communication mediation tools and how these dynamics influence the development of creativity and communication in mathematics as well as students’ (10-12 years old) digital literacy. The data obtained by enquiry, direct observation and document collection were subjected to content analysis. Preliminary results seem to indicate that the implementation of these technologies in educational contexts can provide us with opportunities to effectively change the educational paradigm and to develop mathematical and technological skills, both transversal and specific.

**Framework**

Society faces, today, an unprecedented set of challenges. The creative digital revolution is profoundly changing the way we work, think and connect, with several implications in our lives (Castells, 2007). The social interactions, now markedly mediated by technology, provide for the creation of units that emerge from the common interests of their users and they are true virtual communities, making connectively a defining characteristic of the knowledge society (Siemens, 2004). The construction of a collective intelligence, which materializes a large pool of human knowledge, is the mobilizing idea of this society, where convergence of synergies, expertise and creative ideas encourage collaborative learning based on network interactions (Lévy, 2010).

Thus, implementing cloud based platforms such as Microsoft Office 365 can contribute to develop a truly collaborative culture, both in students and teachers.

Classroom management software can be a powerful mediation tool during students’ ideas presentation and discussions, effectively developing collective constructions of new knowledge. The use of some digital technologies, like Microsoft KODU® (figure 4) can often re-contextualize mathematical situations to students’ own “real-world” and, afterward, meet their expectations accordingly.

The results also suggest that implementing these technologies in educational contexts can provide excellent ways to develop fundamental digital literacies in students and teachers as well as trigger fundamental changes in the way we understand school, its spaces, the “classroom” and their inherent dynamics. It provides us with an opportunity to really change educational paradigm.

**Research Question**

From this standpoint, we carry out a research oriented by the question: What is the influence of technology, as communication and mediation tools to solving tasks in collaborative exploratory mathematical contexts, in the development of creativity and other mathematical and technological competencies?

**Method**

Given the purpose of the research, we developed a qualitative case study involving three groups of students in the 6th grade, during the implementation of a set of mathematical exploratory tasks, in class and in non-formal context.

Data were collected through enquiry - survey, questionnaires and interviews; direct observation - supported by field notes and logbook; and documentary collection mainly related with Yammerr® and OneNote® interactions and tasks’ resolutions (see figure 3).

**Main results and final remarks**

Preliminary results, concerning statistical and content data analysis, suggest improvements on pupil’s performance in mathematical and technological skills and dimensions of creativity, like originality, fluency and flexibility. This study also supports the perception that the creation of network-based collaborative environments and dynamics played a major role in these results. Working in these environments seems to foster student autonomy and motivation levels, particularly in traditionally "hostile" areas, like mathematics.
