31 **Abstract**

32 *Ulva* species, green macroalgae, are widely distributed in the water across the globe,  
33 being one of the most heavily-traded edible seaweeds. Nonetheless, although this genus  
34 has been largely used in scientific studies, its lipidome remains rather unexplored. The  
35 present study sheds light over the lipid profile of *Ulva rigida* produced in a land-based  
36 integrated multi-trophic aquaculture (IMTA) system using liquid chromatography  
37 coupled to high resolution mass spectrometry for molecular lipid species identification.  
38 The lipidome of *U. rigida* revealed the presence of distinct beneficial *n*-3 fatty acids for  
39 human health, namely alpha-linoleic acid (ALA) and docosapentaenoic acid (DPA). A  
40 total of 87 molecular species of glycolipids, 58 molecular species of betaine lipids and 57  
41 molecular species of phospholipids were identified in the lipidome of *U. rigida* including  
42 some species bearing PUFA and with described bioactive properties. Overall, the present  
43 study contributes to the valorization and quality validation of sustainably farmed *U.*  
44 *rigida*.

51

52 **Introduction**

53 Edible macroalgae are a good source of beneficial compounds for human health that  
54 display distinct functional properties that stimulate interest to number of high-value  
55 chains (e.g., medical, nutraceutical and cosmeceutical) (Holdt and Kraan 2011; Leal et al.  
56 2013; Abreu et al. 2014; Rajauria 2015; Roohinejad et al. 2016). *Ulva* spp. have long  
57 been listed in FAO as one of the main macroalgae for commercial use (Naylor 1976).  
58 These popular green seaweeds can be used fresh, dried, or in liquid extracts, either for  
59 direct or processed consumption worldwide (McHugh 2003; Barriga et al. 2017).  
60 Popularly known in the human food market as sea lettuce, *Ulva* spp. belongs to class  
61 Ulvophyceae and can be found in marine and brackish waters, being widely distributed  
62 across the globe. *Ulva* species are well adapted to aquaculture production and can be  
63 successfully cultured by using an integrated multi-trophic aquaculture (IMTA)  
64 framework (Bolton et al. 2008; Msuya and Neori 2008; Marinho et al. 2013; Shpigel et  
65 al. 2017). This innovative and sustainable culture approach mimics the natural ecosystem  
66 of species from different trophic levels, associating the production of fed species (e.g.  
67 finfish) with other extractive organisms, namely marine invertebrates and/or algae, that  
68 incorporate organic and inorganic compounds resulting from the metabolism of fed  
69 species, as well as from uneaten feed. Overall, IMTA promotes a balanced production  
70 framework that is environmentally sustainable and viable from an economic point of view  
71 (Barrington et al. 2009; Chopin et al. 2012). The culture of seaweeds under an IMTA  
72 approach allows the removal of excess nutrients, namely phosphorus and nitrogen, from  
73 wastewater (Neori 2009; Lawton et al. 2013), while enhancing quality and stability of  
74 seaweeds biomass and their biochemical profile (Abreu et al. 2014).  
75 *Ulva* species are consumed directly as “sea vegetables” and used as a food and feed  
76 ingredient. They are also recognized as an important source of valuable polysaccharides

77 (such as ulvans) and oligosaccharides rich in functional groups that bind important  
78 microelements for human and animal nutrition (Lahaye and Robic 2007; Stengel et al.  
79 2011; Berri et al. 2016; Wijesekara et al. 2017). However, to date, the lipid profile of *Ulva*  
80 spp. is still poorly studied at molecular level and few articles have reported their lipid  
81 characterization (Takahashi et al. 2002; Rozentsvet and Nesterov 2012; Ragonese et al.  
82 2014), with most studies solely describing their fatty acid (FA) profile (van Ginneken et  
83 al. 2011; Ragonese et al. 2014; Kendel et al. 2015). While lipids may solely represent  
84 from 1 to 3% of the whole algal dry matter, they do display an important nutritional value,  
85 with emphasis into polyunsaturated fatty acids (PUFAs) from the *n*-3 (e.g., alpha-  
86 linolenic acid, eicosapentaenoic acid and docosahexaenoic acid) and *n*-6 (linoleic acid,  
87 gamma-linolenic acid and arachidonic acid) (Kumari et al. 2010). As essential PUFAs are  
88 not synthesized by humans, they need to be obtained through diet to provide energy and  
89 others health benefits (e.g., reduce the risk of coronary disease and blood cholesterol)  
90 (Ginzberg et al. 2000; Simopoulos 2008; Kendel et al. 2015). Furthermore, PUFAs are  
91 also precursors of important mediators that play a key-role in inflammation and regulation  
92 of immunity (Calder 2001). These biomolecules mostly occur in their esterified form in  
93 polar lipids, namely phospholipids (PLs) and glycolipids. This feature enhances the  
94 nutritional properties of these classes of polar lipids. Additionally, glycolipids isolated  
95 from macroalgae have already been described as displaying bioactive proprieties, namely  
96 antitumoral (Ohta et al. 1998; Eitsuka et al. 2004), anti-inflammatory (Banskota et al.  
97 2013, 2014), antimicrobial (El Baz et al. 2013; Parveez et al. 2017) and antiviral activity  
98 (Wang et al. 2007).

99 The potential added value of macroalgal polar lipids has received a new momentum with  
100 the advent of mass spectrometry-based approaches, which have already been employed  
101 to provide an in-depth characterization of lipidomic signatures of different macroalgae,

102 namely *Chondrus crispus* (Melo et al. 2015), *Codium tomentosum*, *Gracilaria* sp., and  
103 *Porphyra dioica* (da Costa et al. 2015, 2017, 2018). The aim of the present study is  
104 analyzed the lipidome of *Ulva rigida* (C.Agardh, 1823) from a land-based IMTA system  
105 using liquid chromatography high resolution mass spectrometry - based approach. The  
106 data presented will contribute to promote on-going efforts in the responsible, controlled  
107 and sustainable production of high-value macroalgae.

108

## 109 **Material and methods**

110

### 111 ***Reagents***

112 HPLC grade chloroform (CHCl<sub>3</sub>) and methanol (CH<sub>3</sub>OH) were purchased from Fisher  
113 Scientific Ltd. (Loughborough, UK). All other reagents were purchased from major  
114 commercial sources. Milli-Q water was obtained from a water purification system  
115 (Synergy, Millipore Corporation, Billerica, MA, USA). Phospholipid internal standards  
116 1,2-dimyristoyl-*sn*-glycero-3-phosphocholine (dMPC), 1,2-dimyristoyl-*sn*-glycero-3-  
117 phosphoethanolamine (dMPE), 1,2-dimyristoyl-*sn*-glycero-3-phospho-(10-*rac*-glycerol)  
118 (dMPG), 1,2-dimyristoyl-*sn*-glycero-3-phospho-L-serine (dMPS), 1,2-dipalmitoyl-*sn*-  
119 glycero-3-phosphatidylinositol (dPPI), N-palmitoyl-D-*erythro*-  
120 sphingosylphosphorylcholine (NPSM), 1-nonadecanoyl-2-hydroxy-*sn*-glycero-3-  
121 phosphocholine (LPC) were purchased from Avanti Polar Lipids, Inc. (Alabaster, AL).

122

### 123 ***Biomass***

124 The fresh biomass of *Ulva rigida* (C.Agardh, 1823) was produced by ALGAplus  
125 (production site located at Ria de Aveiro coastal lagoon, mainland Portugal, 40°36'43"N,  
126 8°40'43"W) in an IMTA system, harvested in November 2016 (batch U1.4616.L). The

127 ALGAplus IMTA system is composed of a fish organic certified production units  
128 (seabass and seabream) and the seaweed land-based tank system. The water flows from  
129 the fish units, to the seaweed tanks and then to the exit channel that discharges clean water  
130 into the coastal lagoon. Seaweeds are cultivated using exclusively water input from the  
131 fish farm (nothing is added to the water). Stocking densities and water flows are  
132 manipulated in each season to achieve optimal biomass yields and/or specific biomass  
133 quality traits (i.e. chemical composition, colour). After being harvest, all biological  
134 samples were cleaned to remove epiphytic foreign matters, washed with seawater that is  
135 sequentially filtered up to 25 micron and then sterilized by UV and Ozone treatment. The  
136 samples were then frozen at -80 °C, lyophilized, and stored at -80 °C until lipid extraction.

137

#### 138 ***Moisture and ash determination***

139 Moisture was determined by drying freeze-dried samples (250 mg x 5 replicates) in  
140 crucibles on an oven at 105 °C for 15 h. For ash determination, the dried biomass in the  
141 crucibles was first pre-incinerated for 20 min using a heating plate and then placed in a  
142 muffle furnace at 575 °C for 6 h.

143

#### 144 ***Nitrogen determination and protein estimation***

145 Nitrogen content of freeze-dried samples (2 mg x 5 replicates) was obtained by elemental  
146 analysis on a Leco Truspec-Micro CHNS 630-200-200 elemental analyser at combustion  
147 furnace temperature 1075 °C and afterburner temperature 850 °C. Nitrogen was detected  
148 using thermal conductivity. The protein content was estimated from the nitrogen  
149 determination using two nitrogen-protein conversion factors, 6.25 and 5 (Angell et al.  
150 2016).

151

152 ***Total lipid extraction***

153 Lyophilized samples were homogenized in a mortar and pestle until to obtain small-sized  
154 flakes. A biomass of 250 mg of macroalgae was mixed with 2.5 mL of CH<sub>3</sub>OH and 1.25  
155 mL of CHCl<sub>3</sub> in a glass PYREX tube and homogenized by vortexing for 2 min. After  
156 incubation in ice on rocking platform shaker (Stuart equipment, Bibby Scientific, Stone,  
157 UK) for 2.5 h, the mixture was centrifuged (Selecta JP Mixtasel, Abrera, Barcelona,  
158 Spain) for 10 min at 2000 rpm and the organic phase was collected in a new glass tube.  
159 The biomass residue was re-extracted twice with 2 mL of MeOH and 1 mL of CHCl<sub>3</sub>. To  
160 wash the lipid extract and induce phase separation, 2.3 mL of Milli-Q water was added  
161 to the final organic phase, following by centrifugation for 10 min at 2000 rpm. The  
162 organic lower phase was collected in a new glass tube, dried under nitrogen stream. Lipid  
163 extracts were then transferred to amber vials, dried again, weighed, and stored at -20 °C.  
164 Lipid content was estimated as dry weight percentage.

165

166 ***Fatty Acid analysis by Gas Chromatography-Mass Spectrometry (GC-MS)***

167 Fatty acid methyl esters (FAMES) were prepared using a methanolic solution of  
168 potassium hydroxide (2.0 M) (Melo et al. 2015). A volume of 2 µL of hexane solution  
169 containing FAMES was analyzed by gas chromatography-mass spectrometry (GC-MS)  
170 on a GC system (Agilent Technologies 6890 N Network, Santa Clara, CA, USA)  
171 equipped with a DB-FFAP column with the following specifications: 30 m of length, 0.32  
172 mm of internal diameter, and 0.25 µm of film thickness (J & W Scientific, Folsom, CA,  
173 USA). The GC equipment was connected to an Agilent 5973 Network Mass Selective  
174 Detector operating with an electron impact mode at 70 eV and scanning the range  $m/z$   
175 50–550 in a 1s cycle in a full scan mode acquisition. The oven temperature was  
176 programmed from an initial temperature of 80 °C for 3 min, a linear increase to 160 °C

177 at 25 °C min<sup>-1</sup>, followed by linear increase at 2 °C min<sup>-1</sup> to 210 °C, then at 30 °C min<sup>-1</sup>  
178 to 250 °C, standing at 250 °C for 10 min. The injector and detector temperatures were  
179 220 and 280 °C, respectively. Helium was used as the carrier gas at a flow rate of 1.4 mL  
180 min<sup>-1</sup>. FA identification was performed considering the retention times and MS spectra  
181 of FA standards (Supelco 37 Component Fame Mix, Sigma-Aldrich), and by MS  
182 spectrum comparison with chemical databases (Wiley 275 library and AOCS lipid  
183 library). The relative amounts of FAs were calculated by the percent area method with  
184 proper normalization, considering the sum of all areas of identified FAs.

185

### 186 *Lipid extract fractionation*

187 Isolation of polar lipids from pigments was performed using a modification of Pacetti's  
188 method (da Costa et al. 2017). A sample of lipid extract (5 mg) was dissolved in 600 µL  
189 of chloroform and transferred to a glass column with 500 mg of silica gel (40-60 µm, 60  
190 A, Åros Organics) followed by sequential elution with 5 mL of chloroform, 12 mL of  
191 ether diethyl ether:acetic acid (98:2), 7 mL of acetone:methanol (9:1 v/v), and 10 mL of  
192 methanol. Fractions 1 and 2, corresponding to neutral lipids and pigments, were  
193 discarded. Fractions 3 and 4, rich in glycolipids and in phospholipids plus betaines,  
194 respectively, were recovered, dried under nitrogen, and stored at -20 °C prior to analysis  
195 by HILIC-ESI-MS.

196

### 197 *Hydrophilic interaction liquid chromatography mass spectrometry (HILIC-ESI-MS)*

198 Lipid extracts and fraction were analyzed by hydrophilic interaction liquid chromatography  
199 HILIC (Ascentis® Si column, 15 cm × 1 mm, 3 µm, Sigma-Aldrich) on a High-Performance LC  
200 (HPLC) system (Thermo scientific Accela™) with a autosampler coupled online to a Q-  
201 Exactive® mass spectrometer with Orbitrap® technology. Mobile phase A consisted of 25%  
202 water, 50% acetonitrile and 25% methanol, with 1 mM ammonium acetate in relation to

203 the water volume, and mobile phase B consisted of 60% acetonitrile and 40% methanol,  
204 with the same amount of ammonium acetate in mobile phase A. The solvent gradient,  
205 flow rate through column and conditions used for acquisition of full scan LC-MS spectra  
206 and LC-MS/MS spectra in both positive and negative ion modes were the same as  
207 previously described (da Costa et al. 2015; Melo et al. 2015). Initially, 0% of mobile  
208 phase A was held isocratically for 8 min, followed by a linear increase to 60% of mobile  
209 phase A within 7 min and a maintenance period of 15 min, returning to the initial  
210 conditions in 10 min. A volume of 5  $\mu\text{L}$  of each sample, containing 10  $\mu\text{g}$  (10  $\mu\text{L}$ ) of lipid  
211 extract in  $\text{CHCl}_3$ , 4  $\mu\text{L}$  of phospholipid standards mix (dMPC - 0.02  $\mu\text{g}$ , dMPE - 0.02  $\mu\text{g}$ ,  
212 NPSM - 0.02  $\mu\text{g}$ , LPC - 0.02  $\mu\text{g}$ , dPPI - 0.08  $\mu\text{g}$ , dMPG - 0.012  $\mu\text{g}$ , dMPS - 0.04  $\mu\text{g}$ ) and  
213 86  $\mu\text{L}$  of eluent B, was introduced into the Ascentis Si column HPLC Pore column (15  
214  $\text{cm} \times 1 \text{ mm}$ , 3  $\mu\text{m}$ , Sigma-Aldrich) with a flow rate of 40  $\mu\text{L min}^{-1}$  at 30  $^\circ\text{C}$ . The mass  
215 spectrometer with Orbitrap® technology was operated in simultaneous positive  
216 (electrospray voltage 3.0 kV) and negative (electrospray voltage -2.7 kV) modes with  
217 high resolution with 70,000 and AGC target of  $1 \times 10^6$ , the capillary temperature was 250  
218  $^\circ\text{C}$ , and the sheath gas flow was 15 U. In MS/MS experiments, a resolution of 17,500 and  
219 AGC target of  $1 \times 10^5$  was used and the cycles consisted in one full scan mass spectrum  
220 and ten data-dependent MS/MS scans were repeated continuously throughout the  
221 experiments with the dynamic exclusion of 60 s and intensity threshold of  $1 \times 10^4$ .  
222 Normalized collision energy™ (CE) ranged between 25, 30 and 35 eV. Data acquisition  
223 was performed using the Xcalibur data system (V3.3, Thermo Fisher Scientific, USA).  
224 The identification of molecular species of polar lipids was based on the assignment of the  
225 molecular ions observed in LC-MS spectra, typical retention time, mass accuracy, and  
226 LC-MS/MS spectra interpretation that allows to confirm the identity of the polar head  
227 group and the fatty acyl chains for most of the molecular species.

## 228 **Results**

229 The total lipid content of the *U. rigida* was estimated by gravimetry of the lipid extracts.  
230 Also, samples were analyzed for the contents of moisture and ash, proteins, and  
231 carbohydrates and other compounds (estimated by difference). The mean moisture  
232 content (expressed as percentage of freeze-dried sample weight) of *U. rigida* was  $6.41 \pm$   
233  $0.84$ , which was considered to express the content of ash and other components as  
234 percentage of dry weight (DW). The content (% DW) of ash and lipids was  $26.47 \pm 0.51$   
235 and  $2.53 \pm 0.22$ , respectively. Although the factor 6.25 is the most commonly used  
236 indirect nitrogen-to-protein conversion factor, studies have been shown that the protein  
237 content of seaweed is over-estimated by applying factor 6.25 (Hardouin et al. 2016).  
238 Angell et al. (2016) proposed the use of an universal nitrogen-to-protein conversion factor  
239 of 5 for determination of the protein content of seaweeds. Thus, both factors were used.  
240 Using factor 6.25 for protein estimation, the protein content (%DW) was  $17.75 \pm 0.492$ ,  
241 and the content of carbohydrates and other compounds (% DW) was 53.25. Considering  
242 factor 5, the protein content decreased to  $14.20 \pm 0.393$ , while the content of  
243 carbohydrates and other compounds increased to 56.80.

244 The fatty acids (FAs) profile of *U. rigida* revealed the presence of saturated FAs (SFAs)  
245 such as 14:0, 16:0, 18:0 and 22:0, monounsaturated FAs (MUFAs) such as 16:1 and 18:1  
246 and PUFAs such as 16:4, 18:3, 18:4, 20:4, 20:5 and 22:5, as detailed in Table 1. The FA  
247 profile showed 16:0 and 18:0 as the most abundant with relative abundance of 43.41%  
248 and 19.30%, respectively. It is also noteworthy the abundance of the PUFAs 16:4 (*n*-3)  
249 (3.76%), 18:3 (*n*-3) (4.45%), 18:4 (*n*-3) (8.82%) and 22:5 (*n*-3) (3.76%).

250 Polar lipid profile evaluated by HILIC–LC–MS and HILIC–LC–MS/MS allowed the  
251 identification at molecular level of glycolipids, betaine lipids and phospholipids in *U.*  
252 *rigida*. This lipidomic approach allowed the identification, in the case of glycolipids, the

253 acidic glycolipid sulfoquinovosyl diacylglycerol (SQDG) and its lyso form  
254 sulfoquinovosyl monoacylglycerol (SQMG), as well as the neutral glycolipid  
255 digalactosyldiacylglycerol (DGDG) and monogalactosyldiacylglycerol (MGDG).  
256 SQDGs and SQMGs were identified as negative  $[M - H]^-$  ions in the LC-MS spectra.  
257 Overall, 20 molecular species of SQDG and 5 molecular species of SQMG (Table 2 and  
258 Fig. 1) were identified. The most abundant SQDG was assigned as SQDG (34:1) at  $m/z$   
259 819.5, identified as SQDG (18:1/16:0), while the most abundant SQMG was detected at  
260  $m/z$  555.3 and corresponded to SQMG (16:0) (Fig. 1). Typical fragmentation of SQMG  
261 and SQDG species observed in LC-MS/MS spectra as  $[M - H]^-$  ions showed the product  
262 ion at  $m/z$  225.0, corresponding to the anion of the sulfoquinovosyl polar head group that  
263 confirmed the presence of sulfoglycolipids, as seen in the LC-MS/MS spectra of SQMG  
264 at  $m/z$  555.3 (Fig. 1-B) and SQDG at  $m/z$  819.5 (Fig. 1-D). Furthermore, product ions  
265 corresponding to the neutral loss of fatty acyl chains as carboxylic acid (RCOOH) can be  
266 identified and confirm the composition of fatty acyl chains. SQMG species exhibit only  
267 one neutral loss of one fatty acid  $R_1COOH$  (El Baz et al. 2013; da Costa et al. 2015; Melo  
268 et al. 2015). LC-MS/MS spectrum of SQMG (16:0) at  $m/z$  555.3 shows the neutral loss  
269 of palmitic acid (-16:0  $R_1COOH$ , 256 Da) that lead to the formation of the product ion at  
270  $m/z$  299.0 (Fig. 1-B). LC-MS/MS spectrum at  $m/z$  819.5, corresponding to SQDG  
271 (18:1/16:0), shows the loss of two fatty acyl chains  $R_1COOH$  and  $R_2COOH$ , that  
272 correspond to the neutral loss of 18:1  $RC_1OOH$  (- 282 Da) and the neutral loss of palmitic  
273 acid 16:0  $R_2COOH$  (- 256 Da) with formation of the product ions at  $m/z$  537.3 and 563.3,  
274 respectively (Fig. 1-D).

275 The neutral molecular species monogalactosyldiacylglyceride (MGDG),  
276 digalactosyldiacylglyceride (DGDG) and their lyso forms,  
277 monogalactosylmonoacylglyceride (MGMG) and digalactosylmonoacylglyceride

278 (DGMG), were identified in the positive LC–MS spectra as  $[M + NH_4]^+$  ions. Overall 27  
279 molecular species of MGDG, 13 of MGMG, 13 of DGDG and 9 of DGMG were  
280 identified (Table 3 and Fig. 2). The representative LC–MS spectra of MGDG and DGDG  
281 classes are shown in Fig. 2, as well as the LC–MS/MS spectra of the most abundant  
282 species of each class. The predominant MGDG were detected at  $m/z$  760.5. The DGDG  
283 were similarly predominate at  $m/z$  932.6 and 936.7, representative spectrum in Fig. 2  
284 concerns DGDG at  $m/z$  932.6. The MGDG at  $m/z$  760.5 corresponds to MGDG (34:8)  
285 and was identified as MGDG (16:4/18:4), while the DGDG at  $m/z$  932.6 refers to DGDG  
286 (34:3) and was identified as DGDG (18:3/16:0). The typical fragmentation observed in  
287 the LC–MS/MS spectra of MGDG and DGDG species as  $[M + NH_4]^+$  ions allows to  
288 confirm the presence of these neutral glycolipids. LC-MS/MS spectrum of MGDG (34:8)  
289 at  $m/z$  760.5 (Fig. 2-B) indicate the product ion at  $m/z$  563.4, assigned as  $[M + NH_4 -$   
290  $197]^+$ , that results from combined loss of  $NH_3$  (-17 Da) and loss of a hexose (-180 Da)  
291 formed due to the cleavage of the sugar bond near the hemiacetal oxygen bond with  
292 proton transfer to render a diacylglycerol structure. Similarly, in the LC-MS/MS spectrum  
293 of DGDG (34:3) at  $m/z$  932.6 (Fig. 2-D), we can observe the loss of the carbohydrate  
294 moiety (loss of 180 + 162 Da) combined with loss of  $NH_3$  (-17 Da), leading to the  
295 formation of the product ion at  $m/z$  573.5, indicated as  $[M + NH_4 - 359]^+$ . The fatty acyl  
296 chains composition can be inferred by the presence of product ions corresponding to each  
297 fatty acyl group as an acylium ion plus 74 ( $RCO + 74$ ). These ions can be seen at  $m/z$   
298 305.2 and 333.2 in MGDG spectrum (Fig. 2-B) and correspond to 16:4 and 18:4,  
299 respectively. In the case of DGDG spectrum (Fig. 2-D) the  $[RCO + 74]^+$  ions can be seen  
300 at  $m/z$  313.3 and 335.3 and correspond to 16:0 and 18:3, respectively (Murphy 2015).  
301 Betaine lipids identified in *U. rigida* included the diacylglyceroltrimethylhomoserine  
302 (DGTS) and its lyso form monoacylglyceroltrimethylhomoserine (MGTS). The DGTS

303 and MGTS were identified in the LC–MS spectra as positive  $[M + H]^+$  ions. Overall 40  
304 molecular species of DGTS and 17 molecular species of MGTS were identified (Table 4  
305 and Fig. 3). The structural features of betaine lipids were confirmed through the  
306 identification of the typical product ions and fragmentation pathways observed in the LC–  
307 MS/MS spectra. A representative LC–MS/MS spectrum of MGTS and DGTS is shown  
308 in Fig. 3-B and Fig. 3-C, corresponding to the MGTS (18:4) at  $m/z$  494.3 and DGTS  
309 (34:4), identified as DGTS (18:4/16:0) at  $m/z$  732.6. Both LC–MS/MS spectra of MGTS  
310 (Fig. 3-B) and DGTS (Fig. 3-D) showed the typical reported ion of this class at  $m/z$  236.1  
311 corresponding to the combined loss of both fatty acids as keto derivatives ( $R_1CO+R_2CO$ )  
312 (Melo et al. 2015; da Costa et al. 2018). The fatty acyl composition can be deduced by  
313 the losses of fatty acyl chains as acid ( $-RCOOH$ ) and ketene ( $-R=C=O$ ) derivatives. The  
314 ion at  $m/z$  236.1 in LC–MS/MS spectrum of MGTS (18:4) (Fig. 3-B) also represents the  
315 loss of 18:4 fatty acyl chain as keto derivative ( $-258$  Da). In its turn, the LC–MS/MS  
316 spectrum of DGTS (18:4/16:0) (Fig. 3-D) showed the ions at  $m/z$  474.4 and 494.3  
317 corresponding to the loss of fatty acyl chains as keto derivatives ( $-258$  and  $-238$  Da),  
318 matching to 18:4 and 16:0 fatty acids. Moreover, the ion at  $m/z$  456.4 confirmed the  
319 presence of the fatty acid 18:4 since it corresponds to the loss of this fatty acyl chain as  
320 an acid derivative ( $-276$  Da).

321 PLs classes identified in *U. rigida* included phosphatidylglycerol (PG),  
322 phosphatidylinositol (PI), phosphatidylethanolamine (PE), phosphatidylcholine (PC) and  
323 their lyso forms LPG, LPI, LPE and LPC. They were identified in negative mode as  $[M$   
324  $- H]^-$  ions. Overall 5 molecular species of LPG, 17 of PG, 6 of PI and 1 of LPI were  
325 recognized (Table 5).

326 The LC-MS/MS spectra of PG (Fig. 4-A) and LPG species allowed to confirm their polar  
327 head by the presence of the product ion at  $m/z$  171.0, corresponding to  $[C_3H_7O_2OPO_3H]$

328 <sup>-</sup>. On the other hand, the polar head of PI (Fig. 4-B) and LPI is observed at  $m/z$  241.0,  
329 corresponding to an inositol-1,2-cyclic phosphate anion ( $C_6H_{10}O_5PO_3^-$ ). The carboxylate  
330 anions  $R_1COO^-$  and  $R_2COO^-$  allowed the identification of fatty acyl chains (Murphy  
331 2015).  
332 LPE, PE, LPC and PC molecular species were identified in positive mode as  $[M + H]^+$   
333 ions. Overall, 7 molecular species of LPE, 3 of PE, 3 of LPC and 15 of PC were identified  
334 (Table 6). Typical loss of 141 Da was noted in LC-MS/MS spectra of  $[M+H]^+$  ions of  
335 LPE and PE, while the acyl chains were identified in negative mode by the presence of  
336 carboxylate  $RCOO^-$  anions observed in the LC-MS/MS spectra of the respective  $[M-H]^-$   
337 ions. The LC-MS/MS spectra of  $[M+H]^+$  ions of LPC and PC showed the typical product  
338 ion of the polar head at  $m/z$  184.0, while the carboxylate  $RCOO^-$  anions that allowed the  
339 identification of fatty acyl composition were observed in the LC-MS/MS spectra of the  
340 respective  $[M-CH_3COO]^-$  ions (Murphy 2015).

341

## 342 **Discussion**

343 To the best knowledge of the authors, the present study represents the first in depth  
344 characterization of lipidomic signature of the green macroalgae *U. rigida*. *U. rigida*  
345 screened in the present work was produced in a land-based IMTA system, with this culture  
346 approach being considered as a sustainable and environmentally friendly approach to produce  
347 seaweeds and provide high grade safe biomass. When compared to the harvesting of seaweeds  
348 from the wild, this production system has as main the advantages the production of high biomass  
349 loads under controlled and replicable conditions, a less variable biochemical profile that allows  
350 product standardization, as well as the implementation of mandatory traceability protocols for  
351 seaweeds and seaweed-based-products targeting premium markets (Ridler et al. 2007; Chopin et  
352 al. 2012). Fatty acids profile identified was similar with that reported for the same species  
353 (Ak et al. 2014) and for other species belonging to the genus *Ulva*, namely *Ulva lactuca*,

354 *Ulva rotundata*, *Ulva clathrata* and *Ulva intestinalis* (Fleurence et al. 1994; Peña-  
355 rodríguez et al. 2011; van Ginneken et al. 2011; Rozentsvet and Nesterov 2012). As the  
356 PUFAs reported in the present study are essential FAs for humans, the macroalgae *U.*  
357 *rigida* can be an affordable dietary source of these FAs (Li et al. 2009; Cottin et al. 2011).  
358 There are several studies that defend an ideal  $n-6/n-3$  ratio. While  $n-3$  PUFAs exhibit anti-  
359 inflammatory and antioxidant activity, improve the cardiac system and prevent breast  
360 cancer (Mozaffarian et al. 2005; Siriwardhana et al. 2012; Fabian et al. 2015),  $n-6$  PUFAs  
361 tend to promote tumor growth and inflammatory processes (Patterson et al. 2011). One  
362 of the important dietary factor in the obesity prevention is a balanced  $n-6/n-3$  ratio of 1-  
363 2/1 (Simopoulos 2016). Therefore, the consumption of  $n-6$  FAs should be lower than  $n-$   
364 3, in order to avoid several diseases including depressive disorder (Okuyama et al. 1997;  
365 Husted and Bouzinova 2016). In addition, lower  $n-6/n-3$  ratio was associated with  
366 decreased risk of breast cancer in women (Simopoulos 2008). In this context, *U. rigida*  
367 presented a relative abundance of  $n-6$  and  $n-3$  PUFAs of 1.51% and 21.77%, respectively.  
368 Therefore, its  $n-6/n-3$  ratio is lower than 1, highlighting the potential health promoting  
369 properties of this macroalgae for human consumption. Although  $n-6/n-3$  ratios are known  
370 to vary between species and growth condition, to the authors best knowledge *U. rigida*  
371 farmed using a sustainable land based IMTA approach described in the present study  
372 displayed the lowest  $n-6/n-3$  ratio report so far for *Ulva* spp. (van Ginneken et al. 2011;  
373 Kendel et al. 2015). This finding confirms the added value of algal biomass originating  
374 from land-based IMTA, as a higher contents in  $n-3$  fatty acids are commonly associated  
375 with health promoting benefits for consumers (Simopoulos 2002).

376 Identified FAs are esterified into lipid molecules such as glycolipids, betaine lipids and  
377 phospholipids (PLs). The glycolipids detected include sulfolipids and galactolipids which

378 together represented the most abundant structural compounds of chloroplast membranes  
379 (Hölzl and Dörmann 2007) with up to 87 molecular species being identified in *U. rigida*.  
380 There are several studies that demonstrated glycolipids bioactivity from different algae  
381 species, such as antiviral, antibacterial and antitumoral activity (Plouguerné et al. 2014;  
382 Blunt et al. 2016). Wang et al. (2007) described the antiviral activity attributed to SQDG  
383 (32:0) from the green macroalgae *Caulerpa racemosa* (Forsskål) J.Agardh, (1873).  
384 Furthermore, Baz et al. (2013) analyzed the SQMG (16:0) as antitumoral and  
385 antimicrobial activity Other authors demonstrated the inhibitory effect of SQDG and  
386 DGDG from the brown macroalgae *Sargassum horneri* (Turner) C.Agardh (1820)  
387 suggesting the use of these compounds like chemotherapy agents (Hossain et al. 2005).  
388 It is also reported that seaweeds with an abundant presence of PUFAs in their composition  
389 proved to display anti-inflammatory activity by inhibiting nitric oxide release by  
390 macrophages (Banskota et al. 2013; Lopes et al. 2014). Betaine lipids (DGTS and MGTS)  
391 represent a group of polar lipids low studied to date and few studies have characterized  
392 their profile in seaweeds (da Costa et al. 2015, 2017; Melo et al. 2015). Some species of  
393 DGTS identified in *U. rigida* have already been reported in green microalgae like  
394 *Chlamydomonas reinhardtii* P.A.Dangeard (1888) and Chlorarachniophytes (Vieler et al.  
395 2007; Roche and Leblond 2010). It has been suggested that DGTS has the same function  
396 as PC due to their similar zwitterionic structure. Moreover, they are interchangeable with  
397 each other in their roles within the cell (Riekhof et al. 2005). Organisms that contain a  
398 high level of DGTS display either an absence of PC or its presence is very low  
399 (Dembitsky and Rezanka 1995; Kunzler and Eichenberger 1997). Furthermore, Ginneken  
400 et al. (2017) revealed that *Ulva* sp. uses a mechanism rarely reported in eukaryotes, as it  
401 applies the biochemical pathway to produce DGTS that can replace PC in seaweed cell

402 wall (Klug and Benning 2001). It was suggested that the high DGTS/PC ratio occur  
403 communly in species of the genus *Ulva*.

404 Regarding PLs, their beneficial effects have been studied since the early 1900s  
405 (Küllenberg de Gaudry et al. 2012). The positive effect of PLs is supported by several  
406 studies that showed an improvement of the pharmacokinetics of some drugs when  
407 associated with PLs compounds, and a reduction of side effects of some drugs when  
408 administered together, namely indomethacin (NSAID) (Dial et al. 2006; Lichtenberger  
409 et al. 2009). Their cytoprotectively effects and anti-fibrogenic potential have already been  
410 highlighted (Gundermann et al. 2011). Moreover, PLs from marine organisms have  
411 shown a remarkable effect in the regulation of the blood lipid profile in patients suffering  
412 from hyperlipidaemia (Bunea et al. 2004). PLs beneficial dietary effect is the result of  
413 their interaction with cellular membranes influencing a vast number of signaling  
414 processes and also the effect of their fatty acid composition. The great advantage of these  
415 molecules is related with the ability of their esterified *n*-3 FAs to compensate *n*-3 FA  
416 deficiency in a more efficient way than other *n*-3 FA supplements (e.g. as  
417 triacylglycerides or as free FAs). Thus, PLs from foodstuff are major supplies of *n*-3  
418 PUFAs for living systems (Jannace et al. 1992). Furthermore, the antioxidant potential of  
419 PG found in *U. rigida* could be explored (Banskota et al. 2014).

420 Traditionally the study of algal lipids has targeted fatty acids analysis through GC-MS or  
421 GC-FID (Marshall et al. 2002). However, the overall information acquired through these  
422 techniques is limited and solely refers to fatty acids, which in living systems are mostly  
423 linked to polar lipids. In the last decade, with the advent of mass spectrometry, the  
424 commercialization of new devices with higher sensitivity, resolution and sample  
425 screening speed, such as Orbitrap and Q-TOF instruments, allowed to gain a more in depth  
426 knowledge of lipids. The used of liquid chromatography (LC) online with mass

427 spectrometry is nowadays an advanced and promising approach to study lipids in living  
428 systems. The LC-MS platforms allows to identify and quantify molecular structural  
429 details in one single run over very short periods of time (Maciel et al. 2016). In one LC-  
430 MS run, more than two hundred lipid species from different lipid classes are routinely  
431 identified and quantified. Lipid species identification is based on the ions in MS and, in  
432 the case of high-resolution MS, through confirmation of mass accuracy. The structural  
433 details are confirmed by MS/MS data of each molecular species, namely through the  
434 analysis of typical ion fragments. In recent years, this lipidomic approach has been  
435 successfully used to unravel the lipidome of seaweeds (da Costa et al. 2015, 2017, 2018;  
436 Melo et al. 2015) and has become a powerful tool to screen for high value lipid species  
437 with potential biotechnological applications.

438

#### 439 **Conclusion**

440 The mass spectrometry-based approach employed in the present study allowed the  
441 identification of 202 molecular species of polar lipids shared between glycolipids, betaine  
442 lipids and phospholipids, most of them confirmed by their fatty acids composition. The  
443 knowledge of lipid composition of *U. rigida* from a sustainable land-based IMTA system,  
444 comes to inspire future studies of valorization of this seaweed, as its aquaculture  
445 production under controlled conditions will continue to increase as it offers consumers a  
446 safer and more standardized product, from an organoleptically (industry communication)  
447 and biochemical point of view. Moreover, the present study may also serve to stimulate  
448 the consumption of *U. rigida* produced under controlled conditions, as its lipidome  
449 displays a number of molecular species with beneficial bioactive properties that may also  
450 foster new biotechnological applications.

703

704 **Figure 1.** LC–MS spectra in negative ion mode of SQMG (A) and SQDG (C) classes  
705 identified as  $[M - H]^-$  ions. LC–MS/MS spectra of the  $[M - H]^-$  ions of the most  
706 abundant species of SQMG at  $m/z$  555.3 (B) and SQDG at  $m/z$  819.5 (D).

707

708 **Figure 2.** LC–MS spectra in positive ion mode of MGDG (A) and DGDG (C) classes  
709 identified as  $[M + NH_4]^+$ . LC-MS/MS spectra of the  $[M + NH_4]^+$  ions of the most  
710 abundant specie of MGDG at  $m/z$  760.6 (B) and DGDG at  $m/z$  932.5 (D). The ions group  
711 assigned with symbol (\*) are a background.

712

713 **Figure 3.** LC–MS spectra in positive mode of MGTS (A) and DGTS (C) classes identified  
714 as  $[M + H]^+$  ions. LC–MS/MS spectra of the  $[M + H]^+$  ions of the most abundant specie  
715 of MGTS at  $m/z$  494.3 (B) and DGTS at  $m/z$  732.6 (C).

716

717 **Figure 4.** LC–MS/MS spectrum in negative mode of PG (34:4) specie at  $m/z$  741.5 (A)  
718 and PI (34:3) specie at  $m/z$  831.5 (B) identified as  $[M-H]^-$  ions.

719

720 **Table 1.** Fatty acid profile of *U. rigida* sustainably produced under IMTA conditions,  
721 expressed as relative abundance (%). Values are means of seven samples  $\pm$  standard  
722 deviation (SD).

723

724 **Table 2.** Molecular species of SQDGs and SQMGs identified by HILIC–ESI–MS as  
725 negative  $[M - H]^-$  ions. Identification as sulfoglycolipids and fatty acyl composition was  
726 confirmed by the analysis of the LC–MS/MS spectra of each  $[M - H]^-$  ion. C represents

727 the total number of carbon atoms and N the total number of double bonds on the fatty  
728 acyl chains. The most abundant species are marked in bold.

729

730 **Table 3.** Molecular species of MGDG, MGMG, DGDG and DGMG identified by  
731 HILIC–ESI–MS as positive  $[M + NH_4]^+$  ions. Identification as galactoglycerolipids and  
732 fatty acyl composition was confirmed by the analysis of the LC–MS/MS spectra of each  
733  $[M + NH_4]^+$  ion. C represents the total number of carbon atoms and N the total number of  
734 double bonds on the fatty acyl chains. The most abundant species are marked in bold.

735

736 **Table 4.** Molecular species of DGTS and MGTS identified by HILIC–ESI–MS as  
737 positive  $[M + H]^+$  ions. Identification as betaines and fatty acyl composition was  
738 confirmed by the analysis of the LC–MS/MS spectra of each  $[M + H]^+$  ion. C represents  
739 the total number of carbon atoms and N the total number of double bonds on the fatty  
740 acyl chains. The most abundant species are marked in bold.

741

742 **Table 5.** Molecular species of LPG, PG, LPI, PI identified by HILIC–ESI–MS as negative  
743  $[M - H]^-$  ions. Identification of different PL classes and fatty acyl composition was  
744 confirmed by the analysis of the LC–MS/MS spectra of each  $[M - H]^-$  ion. C represents  
745 the total number of carbon atoms and N the total number of double bonds on the fatty  
746 acyl chains. The most abundant species are marked in bold.

747

748 **Table 6.** Molecular species of LPE, PE, LPC and PC identified by HILIC–ESI–MS as  
749 positive  $[M + H]^+$  ions. Identification of PL class was confirmed by the analysis of the  
750 LC–MS/MS spectra of each  $[M + H]^+$  ion. Identification of fatty acyl composition was  
751 performed by the analysis of the LC–MS/MS spectra of respective  $[M-H]^-$  ions for LPE

752 and PE and  $[M-CH_3COO]^-$  ions for LPC and PC, if observed. C represents the total  
753 number of carbon atoms and N the total number of double bonds on the fatty acyl chains.
